LAB PROJECT REPORT

This Report Presented in Partial Fulfillment of the course

CSE412/422: Computer Graphics Lab in the Department of Computer Science and Engineering

DAFFODIL INTERNATIONAL UNIVERSITY

Dhaka, Bangladesh

23/04/2026

DECLARATION

We hereby declare that this lab project has been done by us under the supervision of **Khandoker Nosiba Arifin , Lecturer**, Department of Computer Science and Engineering, Daffodil International University. We also declare that neither this project nor any part of this project has been submitted elsewhere as lab projects.

COURSE & PROGRAM OUTCOME

The following course have course outcomes as following:

Table 1: Course Outcome Statements

CO1	Design and implement fundamental computer graphics primitives and algorithms to construct 2D graphical scenes for real-life visualization problems having complex engineering attribute
CO2	Apply appropriate OpenGL programming techniques, geometric transformations, and graphics algorithms to solve complex real-world visualization problems using modern engineering tools.
CO3	Perform effectively as an individual and as a member of a diverse team to design, document, and implement computer graphics–based projects.
CO4	Create and present a complete computer graphics project by explaining complex engineering activities through effective reports, demonstrations, and presentations.

Mapping Course Outcome (COs) with the Teaching-Learning and Assessment Strategy

The mapping justification of this table is provided in section **4.2.1**, **4.2.2** and **4.2.3**.

Table 2: Mapping of CO, PO, Blooms, KP and CEP

Chapter 1

Introduction

This chapter provides an overview of the Computer Graphics project, including its objectives, scope, and significance. It establishes the foundation by explaining the project's theme, visual concept, and the goals it aims to achieve through graphical modeling and animation.

1.1 Introduction

Computer graphics is the field concerned with the development of graphic material through programming and mathematical tools. It has extensive applications in fields such as games, simulations, and graphical applications. OpenGL is a well-known graphics library which enables developers to draw shapes, transformation, and real-time animation at an efficient rate.

This project is aimed at developing an animated natural environment in OpenGL. Basic graphics, primitives, and algorithms are used to produce all the different elements like the sky, trees, water, and moving objects. The scene is made more realistic with the addition of animation effects such as moving clouds, flying birds, and rainfall. This project illustrates how computer graphics concepts can be practically used in the creation of a dynamic visual scene.

1.2 Motivation

The primary interest of this project is the desire to design visually active scenes by using computer graphics. This project is not just an opportunity to learn the theoretical concepts but put them into a practical use. The animation of a natural environment makes the learning process to be more entertaining and comprehensible.

The other reason was to discover how barebones graphical primitives and algorithms could be used to build up a full and believable scene. The project allows one to learn about how animation can operate in real time graphics through movement like clouds, birds and rainfall. In general, this project was motivated by the aim of acquiring practical experience and enhancing the skills in OpenGL programming and graphical design.

1.3 Objectives

- Dynamic Environment Simulation: To simulate a fully rendered animated natural scene with only simple graphical primitives and OpenGL rendering algorithms.
- Algorithm Implementation: To execute line drawing algorithms like DDA and Bresenham used to create graphical elements.
- State-Based Rendering: To create a system that turns Day and Night on and off, changing the sky color and showing Sun or Moon.
- Real-Time Animation: To create motion like moving clouds, flying birds, rippling water and rainfall based on time.
- Object Modeling: To create complex objects such as trees, benches, ponds and lamp posts out of simple geometric shapes.
- Visual Realism Enhancement: To add color gradients, transparency and light effects to make the scene look more realistic and well-illuminated.

- Modular Design Approach: To subdivide the program into reusable functions to make it more structured and maintainable.

1.4 Feasibility Study

The proposed project is technically viable since the tools that are used like C++, OpenGL, and GLUT are the ones that are widely available and can be easily used to create the 2D graphical applications. The scene rendering and simple animation has been shown in many existing computer graphics projects including simple landscape simulations and interactive environments. These examples demonstrate that it is possible to make animated scenes with OpenGL using normal programming methods.

The project does not demand the use of high-end hardware or complex external resources in terms of development. The algorithms and graphical techniques needed are well-documented and can be programmed with simple knowledge of computer graphics. Other projects related to this are mostly of the form of tutorials and academic examples, which are based on either a static scene or a very minimal form of animation, but this project expands upon these concepts by incorporating numerous animated objects into the same space.

Overall, the project can be done within the time and resources available, and it offers a viable platform to put theoretical concepts into practical use.

1.5 Gap Analysis

Most of the existing projects and tutorials based on OpenGL are centered around drawing a stationary scene or applying single algorithms in isolation. They tend to show simple shapes, simple landscapes, or single animations but do not include several things in a full environment. Consequently, they offer scanty information on the interaction between various graphical elements in a real-time scene.

The other weakness is that most of the examples are not dynamic in nature like changing environment, combined effects, or real-life effects. Such features as switching of days and nights, rains and interaction of objects are not frequently used within one project.

The proposed project fills these gaps by integrating various graphical objects and animation into a single scene. It combines algorithm implementation, object modeling and real-time animation to form more complete and dynamic natural environment.

1.6 Project Outcome

The product of this project is a fully animated natural environment that has been created in OpenGL. Upon the execution of the program, a dynamically generated scene is presented, with the use of objects like sky, trees, pond, and other items being displayed in a cohesive manner in terms of visual appeal.

The scene has animation effects such as moving clouds, flying birds, the effects of water waves, and optional rainfall effects, and has a day and night mode that transforms the overall look of the environment. These characteristics make the output more real, interactive.

The key concepts of computer graphics like implementation of algorithms, modeling of objects, and animation have been effectively implemented through this project. What comes out is the practical and pleasing visual graphical display which is a show of both technical knowledge and application.

Chapter 2

System Architecture/ Scene Description & Architecture

This chapter describes the overall scene design and architecture of the Computer Graphics project. It outlines the main graphical components, their interactions, and the technologies used to create an efficient, visually appealing, and animated OpenGL-based scene.

2.1 Requirement Analysis & Design Specification

2.1.1 Scene Overview

In the project, an animated natural outdoor setting is introduced, which is created with the help of OpenGL. The scene has been made to look like a serene and aesthetically pleasing landscape in which various natural and man-made aspects are brought together into one perspective.

The setting consists of a sky, the ground, trees, pond, bench, lamp post, clouds, birds, and vegetation in the background. The sky also varies depending on time; it has a clear sun in the daytime and a moon with stars in the night, creating diversity to the general scene.

It is not a static scene but a dynamic one. The clouds move slowly over the sky, the birds are actively flying, and the effects of waves can be observed on the surface of the water body in the pond. Moreover, there is also a rain feature, in which rain drops constantly appear and provide a more active background.

Everything is staged in a harmonious manner to give depth and visual consistency. The background trees are rendered smaller to give the impression of distance, and the foreground objects such as the bench and pond are more detailed.

All in all, the scene offers a fully animated setting in which various elements collaborate harmoniously to form a realistic and engaging visual experience.

2.1.2 Object Components

The scene itself consists of several graphical objects, each made from primitive geometric elements, i.e., polygons, lines, circles, ellipses, etc. These items are put together to create a whole nature scene. The main components and geometrical properties are as follows:

Sky and Heavenly Bodies: The sky is prepared by polygons of a rectangle with color gradient. Circular shapes are used in the construction of the sun and moon, whereas small circles are used in the construction of stars.

Clouds: The clouds are created by taking several overlapping circles and ellipses, to give a soft rounded effect.

Trees: Trees are being constructed with the help of polygons to construct the trunk and with a number of circles or triangles to construct leaves. Various trees are utilized, with big foreground and smaller background trees to give depth.

Ground: The ground is depicted with a big rectangular polygon with a slight color contrast and texture to resemble soil.

Pond: Layered ellipses are used to depict the water and its boundary in the pond. To represent the motion of the waves on the water surface, more curved lines are employed.

Bench: The seat, backrest and legs of the bench are made from several rectangles and polygons. Shading and lines are included to provide a more detailed appearance.

Lamp Post: The lamp post is designed in the shape of a rectangle to make the pole and polygonal to make the top. Light sources are represented in the form of circular shapes.

Birds: Small triangles and ellipses are used to create birds with the help of giving the body, wings and the beak. The wing shapes are modulated to imitate motion.

Rain: The rain is depicted with many short line segments which are repeatedly drawn on the scene to create the effect of falling raindrops.

Each of these parts is meticulously placed with coordinate positioning and scaling in order to be proportioned and visually consistent in the scene.

2.2 Use of Modern Tools

This section highlights the modern software tools and technologies employed in the **Computer Graphics project** to enhance visualization, animation control, and rendering performance. It explains how these tools assist in creating dynamic 2D scenes, debugging visual elements, and improving development efficiency.

✓ **OpenGL / FreeGLUT** – Open-source graphics libraries used for rendering 2D and 3D objects, applying transformations, and implementing real-time animations.

✓ **Code::Blocks / Visual Studio** – Integrated Development Environments (IDEs) used for writing, compiling, and debugging OpenGL programs efficiently.

✓ **GLUT / GLFW Libraries** – Frameworks that manage window creation, input handling, and animation timing for smoother real-time rendering.

✓ **C++ Programming Language** – Core programming language used for implementing graphics algorithms (DDA, Bresenham, Midpoint Circle) and modular code structure.

✓ **GIMP / Photoshop / Inkscape (Optional)** – Tools used for creating or editing textures, backgrounds, and digital assets used within the scene.

✓ **Git / GitHub** – Version control systems for managing source code, tracking changes, and collaborating effectively among team members.

2.3 Algorithm Used

In this project, there are two basic line drawing algorithms DDA (Digital Differential Analyzer) and the Line Algorithm of Bresenham that are used to create graphical elements. These algorithms are employed to create lines effectively and create the elements of structure of various objects in the scene.

DDA Line Drawing Algorithm (2D) :

The DDA algorithm estimates intermediate points between two points using progressively smaller steps. It is easy and gives smooth lines with floating-point computations.

Pseudocode:

```
Input: (x1, y1), (x2, y2)

dx = x2 - x1
dy = y2 - y1

steps = max(|dx|, |dy|)

if steps == 0:
   plot(x1, y1)
else:
   xIncrement = dx / steps
   yIncrement = dy / steps

   x = x1
   y = y1

   where steps is some integer:
      plot(x, y)
      x = x + xIncrement
      y = y + yIncrement
```

The Line Drawing Algorithms of Bresenham (2D):

The algorithm proposed by Bresenham is based on integer computations and thus more efficient and fast at rendering lines.

Pseudocode:

```
Input: (x1, y1), (x2, y2)

dx = |x2 - x1|
dy = |y2 - y1|

sx = 1 if x1 < x2 else -1
sy = 1 if y1 < y2 else -1

error = dx - dy
```

```
x = x1
y = y1

while true:
   plot(x, y)

   if x == x2 and y == y2:
      break

   e2 = 2 * error

   if e2 > -dy:
      error = error - dy
      x = x + sx

   if e2 < dx:
      error = error + dx
      y = y + sy
```

DDA Line Drawing Algorithm (2D) :

The DDA algorithm is generalized to 3D by incorporating the z-axis, so that one can generate lines in 3 dimensions.

Pseudocode:

```
Input: (x1, y1, z1), (x2, y2, z2)

dx = x2 - x1
dy = y2 - y1
dz = z2 - z1

steps = max(|dx|, |dy|, |dz|)

if steps == 0:
   plot(x1, y1, z1)
else:
   xIncrement = dx / steps
   yIncrement = dy / steps
   zIncrement = dz / steps

   x = x1
   y = y1
   z = z1

   to i = 0 to steps:
      plot(x, y, z)
      x = x + xIncrement
      y = y + yIncrement
      z = z + zIncrement
```

Line Drawing Algorithm (3D) by Bresenham:

This algorithm takes the algorithm by Bresenham to three dimensions whereby the dominant axis is picked and the rest of the coordinates are updated.

Pseudocode:

```
Input: (x1, y1, z1), (x2, y2, z2)

dx = |x2 - x1|
dy = |y2 - y1|
dz = |z2 - z1|

sx = sign(x2 - x1)
sy = sign(y2 - y1)
sz = sign(z2 - z1)

if dx is largest:
   err1 = dx / 2
   err2 = dx / 2
   while x != x2:
      plot(x, y, z)
      err1 -= dy
      if err1 < 0:
         y += sy
         err1 += dx
      err2 -= dz
      if err2 < 0:
         z += sz
         err2 += dx
      x += sx

otherwise, when dy biggest:
   (the same reasoning with y as the main axis)

else:
   (likewise with z as the primary axis)

plot(x2, y2, z2)
```

The reason why these algorithms are applied:

- DDA is easy and applicable in creating smooth lines.
- Bresenham is economical and quicker because of integer computations.
- The 3D versions add the ability to graphically represent in an advanced way.

These algorithms become the basis of the drawing of structured elements in the scene and assist in comprehending the way low-level graphics rendering is to be performed.

2.4 2D Transformations Applied

This project applies various kinds of transformation indirectly using coordinate manipulation and parameter manipulation for object control. In contrast to using transformation functions such as glTranslatef() and

glRotatef(), most transformations are done directly through modifying coordinates and changing object parameters.

- **Translation** is probably the most frequently used transformation in the project. It is used to produce movement for objects such as clouds, birds, and rain. The position of these objects is changed by manipulating their coordinate values to move them around.

Example:

```
cloudX += 0.002f;
birdX -= 0.003f;
```

By shifting the coordinate values horizontally, we get the illusion of movement.

- **Scaling** is used during the drawing process. Objects such as trees, birds, and benches are scaled down using a scaling factor within their drawing procedures.

  Example:

  ```
  drawBigTree(x, y, s);
  ```

  The value of s affects the scaling of the whole tree structure.

- Rotation is implemented indirectly using mathematical functions. For example, circular and arc drawings use sine and cosine functions to rotate the drawn objects.
- **Reflection and Shear:** Explicit reflection and shear transformations are not directly implemented in this project. However, symmetry is maintained manually in object design (such as trees and birds) by carefully placing coordinates on both sides of a central axis.

Overall, the project mainly relies on translation and scaling for animation and object variation, while rotation effects are achieved mathematically. These transformations help create a dynamic and visually balanced scene.

2.5 Animation Logic

Animation in this project is realised by constant updating the variables related to the objects and drawing the scene anew each frame. The program avoids the use of the static rendering; instead, it employs the time-based modification to produce the natural motion of various things in a smooth manner.

Incremental updates of position variables are used to control the movement of objects. To illustrate, clouds move horizontally in the sky, and birds can fly on one side of the screen to the other by slowly varying the values of their positions. In the same way, a phase variable and trigonometric functions are used to generate the waving effect of water.

Example:

```
cloudX += 0.002f;
birdX -= 0.003f;
wavePhase += 0.05f;
```

A sine function is used to improve the bird animation by simulating wing flapping to provide a more realistic motion of flight. The animation of rainfall is managed by a phase value through which the rainfall is made to

appear to be falling.

The overall animation process is a loop in which:

1. The scene is swept out.
2. New positions and states are applied.
3. Everything is repainted.
4. The screen is re-fresh.

It is a smooth real time animation, produced by this constant update-render cycle. In general, the logic of the animation is not very complex but efficient, and various objects can move in parallel, which contributes to the dynamism and naturalness of the picture.

Chapter 3

Implementation and Results

This chapter explains the step-by-step implementation process of the Computer Graphics project, including the development of objects, application of algorithms, and integration of animations. It also presents the key features, transformations, and visual outputs achieved through OpenGL rendering.

3.1 Implementation

This project is implemented in C++ with OpenGL and GLUT libraries. The whole scene is created through a combination of several modular functions with each of the functions creating a particular drawing of an object like trees, clouds, birds, pond, bench and other objects.

The implementation revolves around basic drawing primitives in the form of polygons, lines, and points that are used to create all objects. Practically, custom functions are generated to make the drawing operations (circles, ellipses, and lines) easier.

Example:

function drawCircle(float cx and cy, float r) void. glBegin(GL_POLYGON); for (int i = 0; i < 120; i++) {float a = 2 PI i / 120; float a = 2 PI i / 120; glVertex2f(cx + r cos(a), cy + r sin(a));); } glEnd(); }

The combination of these basic shapes creates each complex object. An example is the production of trees: the trunks are made of polygons and leaves are made of circles, and clouds are made of more than two overlapping circles.

It is controlled by a main display function that draws all objects in the correct order to ensure that there is the correct layering (background to foreground). This makes sure that objects which are far behind are seen behind those which are closer.

This is done through animation by changing variables within an update or idle function, repeatedly called by GLUT. This operation changes the positions and phases of objects and replenishes the display.

Example:

void update() { cloudX += 0.002f; birdX -= 0.003f; wavePhase += 0.05f;

glutPostRedisplay();

}

Also, such conditional states like day/night mode and rain effect are processed with the help of the use of the Boolean variables. According to these states, various visual elements are dynamically rendered.

In general, the application is done in a systematic process where reusable functions, constant updates, and progressive rendering are joined to create a whole animated scene.

3.2 Output

The product of this project is a graphical window of an animated natural environment, which is exhibited by OpenGL. In the implementation of the program, we will find a complete outdoor scene which will be a combination of various objects, i.e. sky, trees, pond, bench, lamp post, clouds and birds.

The sky is brightly graded with the sun visible in the daytime, and darker with a moon and stars in the night. This shift brings about change in the scene's appearance.

The result is animated and dynamically changing. There is a smooth flow of clouds in the sky, visible wing movement by the birds, and the water-surface of the pond shows effects of waves. Raindrops are dropped over the scene when the rain mode is turned on with small effects of ground splash which makes it more realistic.

The objects in the foreground like the bench and trees are more detailed, whereas the objects in the background are smaller and lighter, creating depth. The lamp post also has a glowing effect in the night mode which further enhances the ambience.

Overall, the work is a graphically stimulating and well-animated image, which shows that the tricks of computer graphics and real-time visualization are used successfully.

3.3 Discussion

The project that has been developed manages to illustrate the use of simple concepts of computer graphics in order to build a full animation scene. The project can bring together various graphical primitives, algorithms and animation techniques in order to create a visual coherent and dynamic environment.

The incorporation of several animated elements into a particular scene is one of the main strengths of the implementation. The animation of objects like clouds, birds, water waves, and rain is done at the same time, making it look more natural and interesting. Day and night modes also contribute to the realism as they alter the overall look of the surrounding.

The fact that modular functions are used to describe various objects is another significant point. This makes the code simple to handle and reuse components like circles, lines and ellipses to create more sophisticated structures.

Nevertheless, there are certain limitations to the project as well. The majority of object positions and movements are fixed, making them less flexible. It also has little user interaction with limited control over the animation as it runs primarily automatically. Also, the scene is restricted to 2D display and lacks more sophisticated features like texture mapping and lighting models.

Nevertheless, the project offers a good insight into the fundamental concepts of graphics and how they can be utilized to create a full animated environment in spite of these shortcomings.

Chapter 4

Engineering Standards and Mapping

This chapter discusses the engineering standards followed throughout the project and maps the project activities to the course and program outcomes. It highlights how the project meets academic and professional requirements.

4.1 Impact on Society, Environment and Sustainability

4.1.1 Impact on Life

The project also leads to the study and comprehension of computer graphics as it offers an interactive and visual means to learn about the concept of graphics. It assists the student and developers have a hands-on experience on the creation of real-time scenes and animations. This knowledge can be used in such areas as game development, simulation, and educational tools that directly influence the contemporary digital life.

4.1.2 Impact on Society & Environment

The project is a kind of natural environment and this can increase awareness of nature and its visual beauty using the digital simulation. Educational applications of such projects may include the extension of the project in order to show changes in the environment or to visualize the ecosystems. The project does not have a direct impact on the environment, but it encourages the concept of technology usage to depict and comprehend natural environments.

4.1.3 Ethical Aspects

In this Computer Graphics project, we follow ethical principles to ensure the design and implementation of graphical scenes are original, respectful, and free from plagiarism or unauthorized content. All visual elements, images, and animations used in the project are either self-created or properly credited to their sources, maintaining academic integrity and intellectual property rights.

Furthermore, we ensure that the project does not include any offensive, misleading, or culturally insensitive visuals. By adhering to ethical guidelines in design, documentation, and presentation, this project promotes creativity, honesty, and professionalism — essential values in responsible engineering and digital content creation.

4.1.4 Sustainability Plan

The project is built with lightweight tools and does not need high-computational resources, making it efficient and sustainable to be used in the long run. It is reusable and can be used in subsequent learning or development. The modular design also allows upgrading and making changes without having to restructure the whole system, which enhances sustainable development practices.

4.2 Complex Engineering Problem

4.2.1 Mapping of Program Outcome

In this section, provide a mapping of the problem and provided solution with targeted Program Outcomes (PO's).

Table 4.1: Justification of Program Outcomes

POs	Justification of Mapping (Project Perspective)
PO1	This project applies mathematical and computational knowledge to create and transform graphical objects using OpenGL. It integrates geometry, coordinate systems, and matrix operations to solve complex visualization and animation problems in computer graphics. (PO1).
PO5	The project incorporates modern computer graphics tools and technologies such as OpenGL, FreeGLUT, and C++ programming to ensure the application of contemporary engineering practices and visualization techniques in real-world scenarios.
PO9	Through collaborative project work, every member was engaged in teamwork, task allocation, and documentation. (PO9).
PO10	Presenting the developed **computer graphics project**, preparing technical reports, and communicating ideas clearly (PO10)

4.2.2 Complex Problem Solving

The following table presents the mapping of the project with the **Complex Engineering Problem (CEP) attributes defined by the Washington Accord framework**. The attributes that are addressed in this project are marked (✓).

Table 4.2: Mapping with complex problem solving.

EP1 Dept of Knowledge	**EP2** Range of Conflicting Requirements	**EP3** Depth of Analysis	**EP4** Familiarity of Issues	**EP5** Extent of Applicable Codes	**EP6** Extent Of Stakeholder Involvement	**EP7** Inter-dependence
✓		✓	✓			

EP1: This project requires us to design, implement, and render complex 2D graphical scenes using OpenGL. These tasks involve applying computer graphics algorithms, transformation logic, and animation techniques, enabling us to develop strong analytical and problem-solving skills in visualization and rendering.

EP3: In this project, we analyze object structures, transformation sequences, and animation timing to create smooth and realistic motion. By breaking complex scenes into smaller components and managing their interactions, we strengthen our ability to formulate and analyze complex graphical problems effectively.

EP4: The project operates within the familiar domain of computer graphics algorithms and OpenGL-based rendering. Students apply known techniques such as line drawing algorithms, geometric transformations, and animation logic to construct structured graphical scenes.

4.2.3 Complex Engineering Activities

Table 4.3 presents the mapping of the project with the **Complex Engineering Activities (CEA)**

attributes. The attributes relevant to this project are marked (✓).

Table 4.3: Mapping with complex engineering activities.

EA1	EA2	EA3	EA4	EA5
✓		✓		

EA1: In this Computer Graphics project, we follow systematic methods to design and document all graphical components, algorithms, and transformations. We organize the project structure, rendering logic, and animation workflow clearly in reports and presentations, ensuring that the technical information is logically presented and easily understood by the audience.

EA3: The project demonstrates innovation by designing and implementing visually engaging graphical scenes that combine multiple graphical elements, transformations, and animation sequences. Students creatively construct scenes such as village environments, traffic systems, or animated natural landscapes, where multiple objects interact dynamically. Through the integration of graphics algorithms, transformation techniques, and animation logic, the project encourages students to develop creative solutions and unique visual representations using OpenGL-based graphics programming.

Chapter 5

Conclusion

5.1 Summary

This project is a proposal to design and develop an animated natural environment in OpenGL. It is a combination of the basic computer graphics principles like line drawing algorithms, object modeling, and animation to form a full-fledged visual scene.

Different objects such as sky, trees, pond, bench, clouds, birds, rain are combined in one environment. The use of animation techniques is used to create a simulated movement which is in real time and thus makes the scene dynamic and appealing. Additional features, such as day and night mode, also contribute to the overall look.

In general, the project illustrates the possibility of implementing theoretical ideas of computer graphics in practice to construct a structured and animated graphical system.

5.2 Limitation

Despite the success of the project in developing an animated graphical scene, it has limitations. The majority of the object positions and movements are pre-programmed, which makes them less flexible and adaptable. The system lacks much interaction with the user, thus there is no dynamic control or modification of the scene by the user.

Also, the project is constrained to 2D world and lacks more complex graphics capabilities, including texture

mapping, realistic light models, or shading. The animation logic, though effective, is fairly basic, and lacks any physics-based behavior, and collision detection.

These shortcomings suggest where improvements can be made to the project and extended in the future.

5.3 Future Work

There are a number of ways in which the project can be enhanced and extended. A potential improvement is to introduce user interaction, which would enable the user to adjust features like day and night, rain on or off or to use keyboard or mouse to move objects.

With more sophisticated OpenGL, the scene could also be prolonged to 3D that would offer a more realistic and immersive space. Visual quality could be enhanced further by adding texture mapping, lighting models and shading techniques.

Physics-based animation, like realistic water movements, the effects of gravity on objects, or collision detection, could be another enhancement. Other items such as cars, humans or interactive items can be added to complicate the scene.

All in all, these improvements would make the project more interactive, realistic and closer to the real world graphical applications.
